

NATURAL RESOURCES AND CONSERVATION

INTRODUCTION

The Natural Resources chapter of the Master Plan reviews the topography, soils, natural communities, and water resources in Jaffrey to inform deliberations regarding the potential for various types and densities of development in Jaffrey. Although natural features can enhance site-specific or area-wide development potential, they can also impose significant constraints to development. Moreover, while the location of roads and highways is an important factor in the location of development, the natural features of the land may be more fundamental to all aspects of development patterns and private land use choices.

This chapter explores Jaffrey's natural environment and the following three core issues:

1. The *fragility* of the Town's natural resources;
2. The threat to ecosystems from land *fragmentation*; and
3. The implications for both the environment and Jaffrey's rural character posed by increasing housing and human *density* in the Rural District.

In today's conservation community, minimizing further disturbance of the physical landscape and avoiding further fragmentation of the unique mosaic of plant and animal communities are considered essential. Protecting the persistence and integrity of natural communities as well as extractive resources (e.g. timber, water, agricultural production, and construction materials) and the fundamental natural processes (e.g. the hydrologic cycle, ecological succession, biodiversity, and even photosynthesis) on which our economic and physical welfare depends is imperative.

Jaffrey has exceptional natural features and resources that make the Town a very desirable place to live, and the Town has maintained a typical New England character with its historic Jaffrey Center and its 19th Century downtown "mill town." These are surrounded by a rural countryside of fields, homes and businesses dispersed along back roads, and by thousands of acres of forested backcountry. This Master Plan chapter will serve to inform and assist the community and its Planning Board in determining how best to preserve the natural environment that the residents currently enjoy while planning for growth.

JAFFREY'S HISTORY OF CONSERVATION EFFORTS

Much of what defines Jaffrey's unique rural character is found in its natural resources: its forests, farmland, lakes and ponds, and – of course – its famous mountain. The people of Jaffrey are stewards of the landscape that identifies our Town.

This was recognized early on by the Town Fathers who in 1883 claimed the summit of the mountain for public ownership and protection. Ever since, individuals and groups alert to threats of commercialization and development have worked tirelessly to conserve large tracts of land on Mount Monadnock and neighboring Gap Mountain. Today over 5,824 acres of conservation land is owned both publicly and privately. Most of it is open to the public for recreational use.

The State of New Hampshire has five tracts within the Town of Jaffrey that comprise 1,346 acres. The largest tract is Monadnock State Park, which is 650 acres. The remainder is state forest property.

The Society for the Protection of New Hampshire Forests owns approximately 2,580 acres, 80% of which may be found along the southern flank of Mount Monadnock. This land is located north of Route 124 and west of Dublin Road. The remainder of the SPNHF parcels are located east of Thorndike Pond, along Great Road, and Old County and Gap Mountain roads.

The Town of Jaffrey owns five parcels that comprise approximately 530 acres. Two of these parcels are located on Mount Monadnock, and a third – Carey Park (which is one of the Town’s forests) – is located along the eastern bank of the Contoocook River and approximately one mile south of the downtown area. The fourth parcel (also a Town forest) is the 4.3 – acre Lacey Lot located on Lacy Road. A fifth parcel of about 13 acres is the Bixler Town Forest located off Fitzwilliam Road. The Town also owns water rights around Mountain Brook Reservoir, and these “rights” extend to an elevation of 1,022 feet or to the 1,022 contour line that surrounds the reservoir. The land included in this water area is approximately 120 acres.

Total Town-protected acreage is 634 acres. The remainder of the protected lands is under private conservation easements (600 acres), and the Town of Troy has a 161-acre reserve for its town reservoir, well, and adjacent watershed. Ownership of public and private lands under conservation easement should be monitored annually by following up with the Society for the Protection of New Hampshire Forests, the New England Forestry Foundation and the Monadnock Conservancy.

As of 2006, much of the northwest quadrant of Jaffrey is protected from future development. Moreover, most of the unprotected land in the extreme northwest corner adjacent to Troy and Marlborough is unsuitable for development due to steep slopes, poor soil conditions, or lack of access. Consideration should be given to adding these lands to the adjacent protected parcels. A particularly attractive area is Perkins Pond, which is located at the base of Mount Monadnock, straddling the Troy/Jaffrey town line, offering a broad view of the mountain.

In the years ahead, greater priority should be given to conservation and land protection in other parts of Jaffrey’s Rural District, particularly to the north, northeast, and southwest of the downtown area. These lands have received less attention than the mountain has to date. Yet they contain rich ecosystems that are under increasing stress along with an extraordinary beauty which complements that of the mountain itself while also contributing to the rural character of Jaffrey so prized by its citizens

Conservation easements and the Current Use Tax Incentive program are two means by which open land can be maintained. It is important to note that at Town Meeting in the last few years, citizens have voted to develop a viable conservation fund to further invigorate and sustain Jaffrey’s land conservation efforts. Requests of this fund will be subjected to a rigorous application process.

The Society for the Protection of NH Forests and the Monadnock Conservancy encourage landowners to place permanent conservation easements on their land. Easements maintain land in private ownership, yet protect the land from any future development. Easements conserve unfragmented acreage and thus assure open views to and from Mount Monadnock, continuous forest, and ponds and lakes encircled by woods.

Under the Current Use program, land parcels over ten acres are taxed on their present use rather than their potential use. An additional 20% tax relief is given when that land is kept open for public recreational use. However, when the use of that land is changed, such from farmland or forestry to house lots, a 10% tax penalty based on the value of the land at that time is imposed.

As noted by Paul Bofinger, former President/Forester of the Society for the Protection of NH Forests, “If you’re going to use anything as a role model for how you protect other good things, (Mount) Monadnock is the best example.” With this in mind, the Town of Jaffrey has a unique opportunity, in its new Master

Plan Update, to take the lead in conserving its other valuable resources – open water sources, aquifers, views and vistas, and valuable farmlands.

Land conservation is a development constraint – it is a legal barrier to development of individual properties.

The following table presents the numbers of properties and acreage of land subject to some manner of “protection” from development in Jaffrey and its neighboring towns, which are depicted in the figure following the table:

Table 28: Protected Property in Jaffrey and Surrounding Towns

TOWN	Number of Protected Properties	Acres of Protected Land	Acres contiguous with Jaffrey *	Percent of Town by Area
Jaffrey	56	5,824	- na -	23%
Dublin	70	4,824	1,903	26%
Fitzwilliam	18	1,260	0	5%
Marlborough	23	1,128	66	9%
Peterborough	102	5,606	72	23%
Rindge	34	3,579	2,163	14%
Sharon	42	4,036	181	40%
Troy	11	1,584	816	14%
Total	356	27,842	5,201	18%

* Acres contiguous with Jaffrey quantify only properties immediately adjacent to Jaffrey, rather than groups of conservation properties.

The 5,824 acres of conservation land in Jaffrey are augmented by more than 22,000 acres of conservation land in the neighboring towns. There are some general trends in the distribution of protected land, and in Jaffrey and neighboring communities: 1) most protected land is at elevations above 1,100 feet, 2) there is very little land conservation near or adjacent to major rivers and streams, and 3) almost half of the land conservation in this subregion is clustered around Mount Monadnock.

The first two trends are typical in New Hampshire – most land conservation is found in higher elevations. Much of the land conservation activity to date has resulted from a rather random coincidence of property owner interests and the availability of an easement holder, rather than on a planning process that might consider variables such as ecological integrity, special habitats, soil resources, community character, or recreational opportunities. The exception to the “accident of connecting willing sellers and willing buyers” has been land conservation driven by popular interest in protecting special places such as Mount Monadnock, Gap Mountain and Little Mount Monadnock.

Figure 13: Conservation Land in Jaffrey and Surrounding Towns

The pages that follow review Jaffrey's natural resources and indicate why many of them are appropriately regarded as constraints on further development.

JAFFREY'S NATURAL LANDSCAPE

Terrain

The terrain of most of the land area in Jaffrey, while irregular, has relatively low relief. The average vertical change in elevation over the distance of a mile is approximately 180 feet. In contrast, Jaffrey's most prominent landmark, Mount Monadnock, is also the namesake of a kind of geomorphic feature: "a mountain of rocky mass that has resisted erosion and stands isolated in an essentially level area."¹ This combination of landforms results in Jaffrey's having the greatest range of elevation within any of the 36 Southwest Region towns. Within Jaffrey, elevation ranges from less than 880 feet above sea level at the point where the Contoocook River flows into Peterborough to 3,165 feet at the peak of Mount Monadnock. Mount Monadnock and the ridge of uplands that bridge Monadnock and Gap Mountain in Troy (a landform known as a saddle: two high points connected by a lower ridge) are distinctly different from the low-relief hills

¹ Excerpted from The American Heritage Dictionary of the English Language, Third Edition (Houghton Mifflin, 1996).

elsewhere in Jaffrey that are pocked with ponds, lakes, and wetlands. That saddle also creates a watershed boundary between the Ashuelot River to the west and the Millers and Contoocook Rivers to the south and east, respectively.

The landforms of Jaffrey are artifacts of the interaction of glaciation and the granite bedrock. Some of the many small hills of central and eastern portions of Jaffrey are small promontories of granite covered with glacial till (a dense mixture of sand, silt, clay, and stones). Others are mounds of till called ‘drumlins,’ that were created by the slow-motion turbulence of the flowing glaciers which had carried sand, silt, clay, gravel, and stones southeasterly over Jaffrey for hundreds of thousands of years before melting away only 12, 000 years ago.

Almost all of Jaffrey is covered with a layer of glacial till, varying in thickness from fractions of an inch to several yards. The exceptions are areas of exposed bedrock, e.g. the summit and ridges of Mount Monadnock, and the sand and gravel deposits of the Contoocook Valley. It is understood that the deep sand and gravel throughout most of New Hampshire’s river valleys are deposited by melt water running out of the melting glaciers. Geological material sorted by running water is known as “stratified drift.” Some stratified drift deposits were formed in streams and lakes that formed on or within the massive glaciers as they melted, and were finally laid on the land as the ice vanished. The deposits in Jaffrey are continuous and have hydrological connections with deposits in Rindge, Sharon and Peterborough; and they extend continuously northward in the Contoocook Valley to the village of Contoocook. The extent of these deposits is widely believed to be the extent of an ancient shallow lake: Glacial Lake Contoocook. The Lake drained when the natural dam of till and ice impounding it was finally eroded. Today Jaffrey’s extensive stratified drift is well known as an important source of both groundwater and sand and gravel for construction materials. Stratified drift can often be identified on the landscape by the flat topography and dense stands of white pines that thrive in the sandy soil where other species cannot.

Scenic Views

Jaffrey’s most prominent physical feature is Mount Monadnock, located in the extreme northwest corner of the Town. With a height in excess of 3,100 feet, the mountain peak is visible from numerous locations throughout the Town. The distinct profile of the mountain provides many scenic views, and these views - - whether they are uninterrupted vistas of the mountain from key locations such as Perkins Pond or fleeting glances through the trees as one travels the numerous roads in Jaffrey -- are an important part of Jaffrey’s heritage. So too are foreground features such as lakes, swamps, streams, forest, and rolling countryside, which – even when viewed alone – are a delight to the eye.

Special vistas, views and scenic areas contribute significantly to a community by enhancing the quality of life and increasing the value of property, while also creating a desirable place to live and work. Consequently, it is important that these views and vistas be protected for future generations and to perpetuate the Town’s scenic majesty.

Farmland

Although Jaffrey’s farmland is relatively small, it is visually attractive while also being commercially attractive as prime real estate for alternative uses.

Agricultural production is a special category of land use that, together with timber management, requires sustaining the physical and chemical properties of the soil as the basis for economic gain – more so than

with other developed land uses. The Cheshire County Soil Survey classifies 89 acres (0.3%) of Jaffrey as “prime farmland soil”, consisting of seven different soil types in 149 discrete patches.²

The prime farmland soils in Jaffrey occur at elevations below 1,320 feet, which excludes them from the slopes of Mount Monadnock and the Monadnock – Gap Mountain saddle. Prime farmland soils are most abundant in a crescent extending from the Jaffrey-Rindge line south of Mountain Brook Reservoir and Gilmore Pond northerly to between Jaffrey Center and downtown, diminishing toward the eastern side of Thorndike Pond. The largest concentration of contiguous prime farmland soil units is found on the Sawyer farm, bounded by Old Sharon Road, Witt Hill Road, and Route 124.

Farmland poses two issues that are in conflict. One issue is the value to the community of preserving farmland as open space, a small but meaningful – and strategically located – component of Jaffrey’s scenic splendor. The second issue is the economic incentive to convert farmland into other forms of developed use, an issue hardly unique to Jaffrey but one that has salience here, as elsewhere.

How Jaffrey resolves the inexorable decline of agriculture and attendant pressures to develop agricultural land with new housing and commercial enterprise will help define the Town’s character in coming decades. Yet attempts to save farmland as open space may prove costly and also counterproductive to the local economy. This is especially so in light of the several constraints on development analyzed in Section III of this chapter, which constraints significantly limit opportunities for future land development in Jaffrey. The result is a thorny dilemma.

Streams and Water Bodies

The irregular topography and dense glacial till of Jaffrey create a high density of streams, wetlands, ponds, and lakes typical of the Monadnock Highlands. Of the 25,565 acres bounded by Jaffrey’s town line, 1,142 acres (4%) are water bodies. The U.S. Geological Survey (USGS) identifies 103 separate water bodies in Jaffrey with a total of 42 miles of shoreline. Please refer to Section III of the U.S. Geological Survey for a description of Jaffrey’s major water bodies (10 acres or more) presented in **Table 29: Great Ponds in Jaffrey**. Some of these larger water bodies have heavily developed shorelines; others are pristine; all are shallow. Jaffrey’s many smaller ponds are also shallow, not much less developed, and emergent vegetation is quite common.

There are approximately 40 miles of perennial streams in town. The Contoocook River is Jaffrey’s largest stream. The Contoocook originates in Rindge as Contoocook Lake, which in turn is created by a dam located in Jaffrey. While only 6 miles of the Contoocook run through the southeast corner of Jaffrey, the River was a formative force in the development of Jaffrey’s downtown as a 19th Century mill town and a regional employment and population center. The Contoocook is unusual among rivers in New England in that it flows northward for its 71-mile run to the Merrimack in Concord, NH. The Contoocook is one of fourteen rivers enrolled in the New Rivers Management and Protection Program. This status has resulted in the development of a Contoocook River Management Plan by the Contoocook & North Branch Local Advisory Committee. That Plan can be viewed at the NH Department of Environmental Services’ “Rivers Program” website.

² See Appendix **Table 30: Soils** for these soil types. The designation is based on the soil’s ability to (1) perennially support pasture, forage, or tilled crop production with little or no nutrient or other soil supplement inputs, and (2) sustain physical management practices (e.g. machinery or livestock) without loss of the soil’s physical properties important to agricultural production.

Wetlands

Wetlands are a valuable, environmentally sensitive resource. They provide an important means of flood and erosion control and pollution filtration. Additionally, they are a source of water, serve as a wildlife habitat, support recreation, and aesthetically enhance Jaffrey's rural ambiance.

The Cheshire County Conservation District describes wetland soils as those soils that are poorly drained or very poorly drained, including muck and peat. They are difficult to quantify given the several disparate sources of electronic data about wetlands, a fact which warrants brief explanation. Wetlands appearing in the USGS topographic maps were delineated from aerial photographs in the 1980s and typically include only non-forested wetlands. The U.S. Fish & Wildlife Service developed the National Wetland Inventory (NWI) in the early 1990s also using aerial photography. The NWI data tend to match the USGS wetlands and also include some additional forested wetlands. The USDA Natural Resources Conservation Service (formerly the Soil Conservation Service) uses a soil classification "hydric soils" to identify soils that are "formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic [lack oxygen] conditions in the upper part." Due to technical aspects of soil mapping, the hydric soils delineations tend to overstate the extent of actual jurisdictional wetlands, defined by the State and Federal governments as "areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions."

The acreages of wetlands identified in Jaffrey by these three sources range from 917 acres (USGS) to 2,056 acres (NWI), and 3,931 acres (USDA). In summary, wetlands are common in Jaffrey. The actual amount of land area occupied by wetlands is somewhere between 917 acres and 3,931 acres – probably more accurately between 2,056 and 3,931 acres - and the USGS wetlands data also indicate 94 separate occurrences.

The State of New Hampshire allows communities to designate "Prime Wetlands." This designation means that the NH Wetlands Bureau, when receiving applications for dredging or filling wetlands, will apply an extra layer of rules defined by state law to applications involving wetlands designated by the town as "prime." The first step in the designation process is an inventory and assessment of the town's wetlands using the "NH Method." Jaffrey does not possess prime wetlands.

Forest Lands

The landscape in Jaffrey is further typified by the prevalence of forest cover. The mosaic of soil and topographic conditions in Jaffrey supports a variety of natural communities of plants and animals, comprising myriad types and species from microbes and algae to white pine and moose. Most of the forest here is likewise a mosaic of distinct plant community types. A Hemlock-Hardwood-Pine "matrix forest habitat" is the dominant forest habitat for approximately 45% of New Hampshire³ and most of Jaffrey. The communities comprising this larger habitat are diverse, ranging from red maple-sphagnum moss swamps and dense hemlock forest to blueberry thickets and hillside forests of sugar maple, American beech and red oak. These occur throughout Jaffrey with the exception of the steepest slopes and top of Mount Monadnock. Despite the prevalence of the Hemlock-Hardwood-Pine forest habitat, the NH Fish & Game Department considers it to be one of the State's "most at-risk habitats." This is due primarily to the habitat's occurring in areas that are also suitable for residential and commercial development and due to invasions of non-native plant and invertebrate species. Preserving the integrity of matrix forest habitats is a necessary goal in conservation planning.

³ Source of habitat descriptions throughout: NH Fish & Game Department. 2006. New Hampshire Wildlife Action Plan.

The second most abundant matrix forest habitat occurring in Jaffrey is Lowland Spruce-Fir Forest. This group of communities is found in western Jaffrey, with concentrations on the southeastern slopes of Mount Monadnock through a range of elevations and slope steepness, but away from the Contoocook River. This habitat occurs in relatively small patches throughout the Monadnock Highlands and Wapack Mountains of southwestern New Hampshire northerly through the Sunapee Highlands. The forest communities here are characterized by wet and seasonally flooded, acidic soils and coniferous tree species, although northern hardwoods and alders also occur.

Two other matrix forest habitats occur only on Mount Monadnock: Northern Hardwood-Conifer Forests on the steep and rocky slopes below the peak of Monadnock, especially on the Pumpelly Ridge, and High Elevation Spruce-Fir Forests at the top of Monadnock among the outcrops and boulders. While the Northern Hardwood-Conifer matrix forest habitat increases in prevalence northward through Dublin to the Sunapee Highlands and dominates medium elevations in the White Mountains, Mount Monadnock, Little Monadnock Mountain in Fitzwilliam and the ridgeline of the Wapack Range west of the Contoocook Valley are the southernmost occurrences in New Hampshire. The summit of Monadnock hosts the lone example of High Elevation Spruce-Fir Forest in Cheshire County, one of five probable locations south of the White Mountains, and the most southerly example in New Hampshire. The communities in this relatively rare habitat are dominated by fir trees, spruce trees, and sphagnum moss in wet, rocky terrain.

Two other terrestrial habitat types are known to occur in Jaffrey: Grasslands, and Rocky Ridges and Talus Slopes. Grasslands occurring in Jaffrey and most of New Hampshire are, of course, man-made. Existing grasslands are associated with current or past land uses such as agriculture, airports, sand and gravel mining, and recreation. In Jaffrey, grassland habitat is found in the farm fields north and east of downtown Jaffrey and the airport.

Like the High Elevation Fir-Spruce Forest habitat, Rocky Ridges and Talus Slopes are restricted to Mount Monadnock and very small isolated occurrences on the topographic saddle to Gap Mountain. Talus slopes are steep slopes often at the base of rock outcrops that are strewn with fallen rocks ranging in size from large stones to small boulders. While Talus Slopes often host a great variety of hardwood and coniferous tree species, and some plant and animal species found nowhere else, they can be unstable and prone to rock slide.

Plant and Wildlife Habitats

The many wetlands, streams, lakes, and ponds in Jaffrey provide aquatic habitats and create riparian habitats on their shores. Wetlands habitats in Jaffrey and throughout central New England are broadly categorized as being Marsh and Shrub Wetlands, Peatlands, or Vernal Pools. Marsh and Shrubland Wetlands include a variety of plant communities and hydrologic conditions. These range from wet meadows of grasses and sedges, cattail marshes, and alder-dogwood-arrow wood thickets in standing water, to red maple forests flooded periodically each year. Moreover, all of these can occur at the edge of waterbodies, in the course of streams wending through the forest, or isolated from other surface water in low spots on the landscape. Most of the many small and large wetlands observed in Jaffrey are Marsh and Shrub Wetlands Habitats.

Peatlands are characterized by acidic water chemistry. The special plant and animal communities associated with that often include sphagnum moss and carnivorous plants, but also a wide variety of herbaceous plants, shrubs and trees. Their assemblages are peculiar to Peatland habitats. Peatland wetlands are not uncommon in Jaffrey, but tend to be smaller and are considerably less common than Marsh and Shrub Wetlands, and as such can be considered at risk.

Vernal Pools are essentially depressions where water ponds form in the spring during snow melt and spring rains due to topography and soil conditions. The duration of ponding is sufficient to support the aquatic

phase of the life cycles of a number of invertebrates and amphibians – and, in fact, are essential to the same. In the glacial till uplands of New England, vernal pools are many and small, often only several square yards in area. While the water table may be sufficiently near the surface in and around vernal pools throughout the year to support indicator plant species, it more often is not, leaving the location of vernal pools difficult for the untrained eye to identify when not flooded.

The aquatic habitats of Jaffrey's lakes, ponds and streams are classified as part of a larger group: the Southern [NH] Upland Watersheds, which begin with the land draining to the South Branch Ashuelot River in Fitzwilliam and Troy, Lake Monomonac in Rindge, and the Gridley River in New Ipswich. They extend northward through the Monadnock and Sunapee Highlands and beyond. These include riparian habitats along stream channels and the near-shore and open water habitats of lakes and ponds. Riparian habitats are transitional between water and upland and often support unique species. Riparian habitats may extend only a few feet from the water's edge or hundreds of yards (e.g. floodplains) and in general are easily lost to development.

Considering the earlier estimates of 42 miles of waterbody shoreland and 40 miles of perennial streams, and assuming a conservative average width of 25 feet for riparian habitats adjacent to streams, lakes and ponds, Jaffrey could have something on the order of 488 acres of riparian habitat. Of course, much of this shoreland is developed today, particularly on the Great Ponds and the Contoocook River in the downtown area.⁴

Wildlife

The landscape in Jaffrey is also teeming with animal life, from microscopic invertebrates living in the film of water between soil particles to moose and black bear ranging across thousands of acres of forest. It is important to remember that the land, water and plants are not inert media in which animals live but rather that each is a part of the whole, an interactive system that is at once constant and yet is constantly being changed by what happens next.

The animals found in Jaffrey are typical throughout central New England. Mammals inhabit or use all habitats in Jaffrey. Some are far ranging and can use or require parts of many different habitats in the course of their year and lives, such as moose, black bear, bobcat, coyote, and fisher. Others have smaller home ranges and more limited preferences or requirements of habitat conditions, such as white-tailed deer, otter, porcupine, fox and other fur-bearers, including beaver, muskrat, mink, and weasel. Rodents can have broad habitat requirements, such as white-footed deer mice and other species of woodland mice, meadow voles, chipmunk, and red and gray squirrels. Still others have more limited requirements of habitat conditions, such as the northern flying squirrel, red-backed vole, and several species of bat. And so it goes for the variety of bird species, reptiles, amphibians, fishes, and the myriad invertebrates from snails and insects to crayfish and freshwater mussels.

The NH Natural Heritage Inventory Bureau reports that one reptile species, two insect species, seventeen plant species, and two plant communities that are considered endangered, threatened or warranting monitoring in New Hampshire are known or suspected to occur in Jaffrey. Half of these are associated with Mount Monadnock and Gap Mountain. Reported or suspected occurrence of the others is widely dispersed. The Bureau prohibits publishing the names of species and communities of concern by geography in order to protect the resource from disturbance or collection. It should also be noted that some of the reported occurrences date from the 19th Century and have not been corroborated since then, and that the Bureau's

⁴ For a more detailed inventory of habitats please see "Natural Communities Expected to Occur in the Town of Jaffrey" in "Natural Communities of New Hampshire" published by the NH Natural Heritage Inventory Bureau

inventory is not the result of systematic area-wide research and therefore under-represents the numbers and variety of species and communities of concern in Jaffrey.⁵

The variety, distribution and requirements of plants and animals across Jaffrey's terrain, points to the urgency of preserving the mosaic of landscape conditions. Maintaining landscape conditions intact, where possible, will help to accommodate the full range of changes through seasons and years. The goal must be to avoid or minimize further fragmentation of the natural landscape by development and other disturbances.

Summary

As revealed in several surveys, including the one conducted in December 2005, open space and the Town's rural character are highly valued by the citizens of Jaffrey. Preserving both in the face of pressures for development is an important challenge to town planning.

Open space provides many benefits:

- Maintenance of rural character
- Preservation of pleasant scenery
- Revenue from tourism
- Keeping land unfragmented and providing buffers between developments
- Wildlife habitat and corridors protection
- Groundwater protection, water retention, and groundwater recharge
- Flood control
- Food production
- Air purification and the production of oxygen
- Recreational opportunities
- Low maintenance costs and a net cash flow favorable to the Town

It is essential that Town Planners recognize the role that open space plays in giving Jaffrey its character. Strategies must be developed that will best maintain this rural character within a framework of future economic growth while also contributing to the long-term sustainability of the community.

The next section examines the significance for development of five features of Jaffrey's landscape: steep slopes, wetlands, floodplains, aquifers, and surface water.

DEVELOPMENT CONSTRAINTS

Landscape conditions can impose limitations on development by requiring extraordinary costs for engineering, construction and/or maintenance of developed land uses. Development under some landscape conditions may also jeopardize or diminish public interest in natural resource values, such as water supply, clean air, and productive farm land, or more esoteric matters such as scenic qualities and biodiversity.

Physical conditions that may render areas less desirable for development include steep slopes, seasonally wet soils, wetlands, floodplains, and soils that are shallow to bedrock or water table. The Soil Survey of

⁵ The NH Fish & Game Department published in 2006 the "New Hampshire Wildlife Conservation Action Plan" which provides a description of habitats which are at risk or are associated with plant and animal species at risk in New Hampshire. **[NOTE: GIS data from that report is available for use in local planning from SWRPC.]** See the NH Natural Heritage Inventory Bureau and NH Fish & Game Department for inventories and further information about plant and animal species of concern.

Cheshire County, New Hampshire, published by the US Department of Agriculture Soil Conservation Service, 1982 and the Soil Potential Ratings for Development; Cheshire County, NH, prepared by the Cheshire County Conservation District in 1984 are reliable, comprehensive source of information regarding development constraints.

In addition to difficult or sensitive landscape conditions, other conditions to be considered here include important farmland soils, stratified drift aquifers, and properties that are legally protected from development (a.k.a. conservation lands). Approximately 68% of Jaffrey is subject to one or more development constraints.

Steep Slopes

Slope is a major consideration for Jaffrey's future development. Generally speaking, the steeper the land, the greater the possibility for erosion and sedimentation, and the more problems can be encountered in siting wells and septic systems.

Steepness is measured in terms of slope, which is defined as the change in elevation (vertical distance) over horizontal distance; the more abrupt the change in elevation, the steeper the slope. Slope is measured and expressed as a percentage that represents the relationship between elevation and horizontal distance.

Typical categories that might be seen on a slope map are 0-8%, 9-15%, 16-25%, and over 25%. Land in the 0-8% slope category is generally preferred for all types of development. Gradual slopes are most favorable for building roads, and public water and sewer facilities can be installed at the least cost to the community. Also, excavations for most structures can be done at a minimal cost, and the erosion associated with such work can be reduced easily on-site. The exceptions to this would be wetland areas and floodplains because they occur primarily in the 0-5% slope range. An examination should be made as to the environmental function of such wetland and floodplain areas, as well as the risks that might be inherent in development before such lands are utilized for building sites.

As slopes increase to 9-15%, the land is more suited to less intensive forms of development. Carefully placed residential dwellings and some agricultural uses (orchards and field crops) may be suitable for this terrain. As development approaches a 15% gradient, it requires more careful consideration for all types of development. Once a slope exceeds a 15% gradient, all forms of development require special consideration before permitted, and slopes greater than 25% are especially problematic. Steepest slopes often harbor special plant and animals communities as well. Disturbance of steep slopes by deforestation or excavation, and even timber harvest, can create erosion problems. Forestry practices on such slopes must be confined to low-impact operations, including minimal basal area cutting and skid roads designed for steep slope harvesting with proper erosion controls in place.

When developing steep terrain, the potential for environmental damage increases as the slope gradient increases. Steep slopes consisting of sands and gravels left after the excavation of an area will quickly gully and erode. Erosion control barriers should be in place at the time of excavation, and prompt re-seeding and re-grading should take place afterwards. The Surface water run-off rates and erosion factors increase as slope steepness increases. This will cause sedimentation of the surface waters down slope and will clog stream channels and rivers if no erosion controls are in place.

In terms of development, slope is a significant limiting factor in Jaffrey. Approximately 7,800 acres (30% of the Town's total area) consist of slopes that are 15% or greater, requiring significant review, on a case by case basis, of all development in these areas or, above a 25% gradient, virtually no capacity. Moreover, while Mount Monadnock accounts for more than half of this total, there are steep slopes throughout the

Town, notably along its eastern perimeter and in the southwestern quadrant. The Steep Slopes Map shows the location of these slopes⁶.

It bears emphasizing that the principal conservation issue concerning steep slopes is not soil quality but soil erosion. Many of the Town's steep sloping areas contain soil properties that are rated high in terms of development potential. Many areas along the Town's side slopes contain deep, well-drained soil deposits. Despite having favorable soil properties, these areas should still be considered unsuitable for development due to their erosion potential. In effect, slopes and soils are not proxies for each other. And where steep terrain and soils with low infiltration rates combine together to produce high surface water runoff rates, the erosion potential is especially severe.

To be sure, there are several large land areas scattered throughout Jaffrey that have both good soil properties and minimal slopes. These lands are located primarily in the southern half of Jaffrey. However, much of this land is already developed; and the prospects for future development are limited by the fact that abutting the Town's existing road network are many wetland areas and hills with steep slope gradients.

The situation described above makes the issue of hillside development a critical one for Jaffrey. Hillside development should be evaluated in terms of potential soil erosion, septic system placement, water well placement, roadway and driveway construction, surface water runoff, and general aesthetics. In such areas, the presence of municipal water and sewer can be a slightly mitigating factor in terms of construction impact. However, other aspects of construction (e.g., driveways, lot preparation) still present the potential for erosion; therefore, strict erosion controls need to be in place. Soil properties should be considered in conjunction with slope gradients when evaluating a site's erosion potential.

Wetland Soils

The Cheshire County Conservation District describes wetland soils as those soils that are poorly drained or very poorly drained (including muck and peat). Jaffrey has a moderate amount of wetland soils areas that are scattered throughout town (Mount Monadnock being the only exception). Only 3,870 acres (or approximately 15% of the Town's total land area) can be described as having wetland soil characteristics. This wetland acreage total can be broken down further into 1,028 acres of poorly drained soils and 2,842 acres of very poorly drained soils⁷. The locations of the town's wetland soil areas are delineated on the accompanying Wetland Soils Map.

As stated earlier in this chapter, wetlands serve a number of important functions that are not only beneficial to the environment but to people as well. Wetlands act as buffers along shoreline and control erosion and sedimentation; they serve as flood abatement and protection areas; wetlands filter pollutants from water, are fish and wildlife habitats and are a recreational resource for fishing, hiking, canoeing and many other activities. Wetland protection is a vital step in creating healthy, sustainable communities. Regulatory practices used to preserve wetlands create constraints on development, such as where septic tanks can be located, permitting requirements for roads crossing wetlands, use restrictions within wetlands and wetland buffers, and building setbacks from wetlands.

Floodplains

Floodplains are land areas that are characterized by annual or periodic flooding. Preserving floodplains in a natural state preserves the plant and animal communities there and provides natural storage of floodwater, thereby avoiding or minimizing downstream flooding and erosion. However, due to floodplains typically

⁶ See Table 31: Steep Slope Soils in the Appendix and the Steep Slope Map

⁷ See Table 32: Wetlands Soils in appendix

being level ground with sandy loamy soils, they are also often suitable for development, at an earlier time for cropland and today for residential and commercial uses. Yet development on floodplains displaces natural communities, displaces natural flood storage and puts buildings, infrastructure and people in harm's way in the event of a flood.

Floodplains actually have two parts: the floodway and the floodway fringe. The floodway includes the channel and an additional area that often carries excess flow. The floodway fringe (more commonly known as the 100-year floodplain or the Special Flood Hazard Area) is a broader area over which floodwater may spread, but where the flow velocity is slower. This is an important distinction for land use planning, since some uses can safely occur in the Special Flood Hazard Area, but not in the floodway, such as agriculture, parking and recreation.

The Federal Emergency Management Agency (FEMA) maps floodplains for municipalities. The boundaries of the floodplains are estimated by interpolated between data associated with cross sections of stream channels, based on observations of past flooding. Flood Insurance Rate Maps define the 100-year floodplain (meaning there is a 1 out of 100 chance of flooding in any given year), and an area of 500-year floodplain (a 1 out of 500 chance of flooding in any given year).

New Flood Insurance Rate Maps (FIRM) for Jaffrey became effective May 23, 2006. Jaffrey participates in the National Flood Insurance Program by adopting the FIRM and a local Floodplain Development Ordinance, thereby qualifying homeowners in the floodplain to purchase federal flood insurance for their property. The Ordinance requires that the lowest enclosed floor in new construction or substantial improvements to homes located in the Special Flood Hazard Area must be at or above the base flood elevation.

Floodplain soils comprise about 1,019 acres in Jaffrey, or 4% of the Town's land area⁸. Although found throughout the Town, there are four major concentrations of floodplain soils, as revealed in Water Resources Map: (1) at the northern end of Contoocook Lake and along the Contoocook River, both below and above downtown Jaffrey; (2) just north of the Black Reservoir (3) along Mountain Brook above Laban Ainsworth Pond and between it and the northern inlet of Mountain Brook Reservoir; and (4) between White's Pond and Bailey Pond.

The USDA soil survey also identifies soils that are prone to flooding, typically during spring run-off, and during annual or periodic flooding. They consist of fine particles of sand, silt and organic matter deposited by floodwater and are almost always level ground. As noted in the Land Use Chapter, these same soils are often excellent agricultural soils by virtue of their structure and nutrient content.

Aquifers

Aquifers are geologic formations (either sand and gravel, referred to as stratified drift or bedrock) that by virtue of their physical structure and location on the landscape can provide water through drilled wells in sufficient quantities to support human uses. Characteristics of high-value aquifers include being situated downstream in a watershed, being in a watershed with a preponderance of natural forested land cover, and having a physical structure that is highly permeable – open spaces between particles of sand and gravel or interconnected networks of cracks in bedrock to both store and transmit water. Aquifers are re-supplied primarily by water falling as precipitation. Rain and snow melt move downward through soil, sand and gravel and/or cracks in bedrock to a saturated zone where the spaces between particles and cracks in rock are filled with water.

⁸ See Table 33: Floodplain Soils in Appendix

Aquifers of low to high value occur in southwestern New Hampshire as unconsolidated deposits of sand and gravel, or in bedrock fractures. The unconsolidated deposits in this region are principally stratified drift deposits (sand and gravel sorted and deposited by running water from the melting glaciers) that are usually in valley floors. These materials have abundant pore space to store water, and pore space may amount to more than 30 percent of the total volume of the deposit. Consequently, stratified deposits at the bottom of watersheds are good aquifers. The U.S. Geologic Survey and the NH Department of Environmental Services completed a comprehensive study of the extent and aquifer potential of stratified drift in the State in 1993. While the USGS study can be enhanced with further site- or area-specific investigation, the findings are considered reliable and much more accurate than previous reconnaissance studies.

The USGS study indicates extensive stratified drift deposits throughout southeastern Jaffrey. These deposits are continuous with stratified drift “upstream” or, more accurately, up-gradient in Rindge and Sharon and “downstream” in Peterborough. Potential yields from the deposits in Jaffrey range from low to medium. Aquifers are described by a unit of measure “transmissivity”, reported as “feet-squared-per-day”, which accounts for both the amount of water stored in an aquifer available for withdrawal and the ease with which the removed water will be replaced. The transmissivity of Jaffrey’s stratified drift deposits is estimated to range from less than 1,000 to 4,000. Transmissivity less than 1,000 is considered marginal for public or commercial wells. Jaffrey’s existing municipal wells are located in the medium yield deposits.

The situation of the stratified drift extending throughout parts of Jaffrey, Rindge and Sharon creates a water management issue for Jaffrey in that, while water in Jaffrey’s aquifer may be contributed from land area in the other towns, Jaffrey does not have land use authority in the neighboring towns.

Protecting groundwater in aquifers for individual private wells or public wells requires protection of environmental quality throughout the contributing watershed(s). This includes pollution prevention (including septic system maintenance) and minimizing impervious surfaces (rooftops, pavement and compacted earth) or otherwise ensuring a natural regimen of stormwater run-off versus infiltration to groundwater. For this reason, many states and towns have created regulation to control development in watersheds that supply the water to the aquifer area that is used as a public water supply.

Fractured bedrock can be highly-productive aquifers, especially when overlaid by a layer of sand gravel, which allows the recharge to occur directly from above. Most domestic water wells in Jaffrey are drilled into bedrock; and while many have low yields, bedrock fractures can yield vast amounts of water and sometimes transmit great volumes of water over many miles. Bedrock aquifers are more difficult to characterize, requiring labor-intensive, site- or area-specific technological study. At present there is little detailed information about the qualities of bedrock as an aquifer in New Hampshire. However, the USGS is currently conducting a geologic study of bedrock aquifers in the State, which will provide information similar to the 1993 stratified drift study.

Glacial till will typically provide very low yields of water to a well. The high content of very fine particles of clay and silt in till creates a situation where till can absorb a tremendous volume of water, like a sponge. However, electro-chemical interaction between water molecules, silt and clay essentially trap water in till. While the water in till is available to the flora and fauna of soil and plant growth above ground, till is a very poor aquifer.

Surface Water

Of Jaffrey’s total land area of 25,565 acres, 1,142 acres (4%) are bodies of water. The U.S. Geological Survey (USGS) identifies 103 separate water bodies in Jaffrey, with a total of 42 miles of shoreline.

Jaffrey's 12 Great Ponds – water bodies 10 acres or greater in size – are prominent natural features (Table 29; see also Water Resources Map). These ponds and shorelands are cherished as home sites and for their recreational and habitat values.

Table 29: Great Ponds in Jaffrey

Pond	Acres (in Jaffrey)	Maximum Depth (in meters)	Mean Depth (in meters)
Ainsworth Pond	15	NA	NA
Black Reservoir	10	1.5	0.6
Cheshire Pond	27	3.0	1.0
Contoocook Lake	215	6.4	2.2
Cummings Meadow	42	1.8	0.6
Frost Pond	56	3.7	2.1
Gilmore Pond	115	13.1	3.7
Gilson Pond	12	1.0	0.4
Hodge Pond	14	NA	NA
Mt. Brook Reservoir	194	3.4	1.0
Parker Pond	20	2.3	1.4
Thorndike Pond	224	7.0	3.4

Surface water is not commonly regarded as a constraint on development. However, there are three reasons why Jaffrey should treat the protection of its surface water as a priority concern having potential significance for further development along and near the shorelines of its Great Ponds, in particular.

- 1) Along with bedrock wells, Jaffrey's surface water is the most likely source of water to meet the Town's future needs for an expanded water supply.
- 2) Jaffrey's Great Ponds are uniformly shallow, making them especially vulnerable to pollution caused by over-development of their shorelines (Contoocook Lake being a prime example).
- 3) Measures to protect long-term water availability and quality are necessary in the short term lest more of these bodies be compromised and their future use as water sources be impaired or rendered more costly.

All of this is underlined by the fact that much of Jaffrey's shoreland development consists of seasonal residences on small-sized lots with on-site septic systems. This type of development poses a potential threat to the water quality of the water bodies affected. As more of these seasonal residences are converted to year-round homes, there will be increasing incidents of septic system failure, thus increasing the threat of contamination. One solution to this problem would be greater setback requirements for septic systems and structures.

In sum, Jaffrey would be wise to take immediate and permanent action to safeguard its future water supply, as recommended in the *Final Report* of the Town's Ad Hoc Water Study Committee (September 17, 2004).

Implementing water protection overlay zoning and other protective measures are especially recommended for Mountain Brook Reservoir.

Moreover, the Town would be well advised to revisit the existing Shoreland Overlay District to ensure its adequacy in the face of increasing pressures for perimeter development of all Great Ponds in the years ahead.

This committee asks additionally that Bullet Pond be closely monitored. Although Bullet Pond is located in Rindge, Jaffrey owns it and the land around it. Bullet Pond is a well-protected surface water source and served for many decades as a source of very high quality drinking water for Jaffrey. Some NHDES officials now agree that their decision to stop using Bullet Pond, circa 1990, was unfortunate. As such, its potential future value to Jaffrey is very high. It is in Jaffrey's interest to actively monitor all development activity in the watershed of Bullet Pond and to communicate our interest in protection of this resource to the current generation of planning officials in the Town of Rindge.

Summary

The natural resources of Jaffrey need to be protected from the impacts of development. The environment, and our continued use of it, depends upon active stewardship by the community. Regulations related to development on steep slopes, surrounding wetlands, within floodplains, and within aquifer recharge areas need to be stringent enough to ensure the ecological health of these areas as well as the public health benefits that they provide.

CHAPTER SUMMARY AND CONCLUSION

The fragility of our Town's natural resources, the threat to ecosystems from land fragmentation, and the implications for both the environment and Jaffrey's rural character posed by increasing housing and human density in the Rural District must be recognized. Through the creation of an Open space/Natural Resource Subcommittee, perhaps jointly with the Jaffrey Conservation Commission, the Planning Board could study how best to provide stewardship of our natural resources. This committee would review and strengthen relevant ordinances. Our rural ambiance will be sustained only through an on-going process of reconciling conservation with development.

Jaffrey must consider carefully the reality that approximately 68% of our Town's land area is subject to one or more of five natural constraints to development (steep slopes, wetland and other vulnerable soils, floodplains, aquifers, and surface water). This committee suggests that a natural resources section be created in the new Land Use Plan. A review of all ordinances pertaining to these natural constraints must be done. Recognizing inevitable tradeoffs with legitimate development, expert opinion should be sought on how best to protect these constraining, natural, physical features.

It would be helpful if a 3-tiered map, 1st tier Unfragmented Rural Land, 2nd tier Other Rural Lands, and 3rd tier Targeted Development Areas is developed. This could be done in conjunction with the Jaffrey Conservation Commission and would be a helpful guide for decisions concerning conservation and development.

The centrality of Mt. Monadnock's topography, scenic splendor of Jaffrey is known and respected. It is necessary, too, to recognize the significant and vulnerable natural resources, scenic attractions, important plant and wildlife habitats, and agricultural lands of high soil quality of the Rural District outside the Mountain Zone. Both the Mountain Zone and Rural District deserve to be well protected. This committee suggests that high-density, multiple-use development be directed to the downtown hub area. By enlarging this hub area, commercial and industrial expansion as well as the need for affordable housing could be met.

Jaffrey's northern, northeastern, and southern peripheries' natural resources, open space, and rural character can be protected by allowing only low-density housing in these areas.

We wish to make a final comment concerning Jaffrey's farmlands. Within the current state of both the local and national economy, agriculture no longer provides a sufficient primary income for most families or individuals and therefore there is a significant threat to existing farmland as large tracts are being sold primarily for residential development. However, there has been a rise in the use of small scale farming for personal use, farming as a secondary income source, and an increase in the production of value-added farm products being produced by small farms. However, there is still a significant threat to farmlands within Jaffrey. Maintaining agricultural lands in Jaffrey in their current state through the use of conservation easements, Open Space Residential Developments, Transfer of Development Rights and other regulatory policy should be a goal of Jaffrey in order to mitigate the impacts of development on an important town resource.

MAPS & APPENDICES

Footnote 5 on Page 108:

Table 30: Soil Types

Symbol	Soil Type	Characteristics
24B	Agawam	Very fine sandy loam, 3-8% slope
72B	Berkshire	Fine sandy loam, 3-8% slope
76B	Marlow	Fine sandy loam, 3-8% slope
108	Hadley	Silt loam, very level
142B	Monadnock	Fine sandy loam, 3-8% slope
168B	Sunapee	Fine sandy loam, 3-8% slope
513B	Ningret	Fine sandy loam, 3-8% slope

Footnote 9 on Page 114:

The soils listed below are the fourteen soil types occurring in Jaffrey that are associated with excessively steep slopes:

Table 31: Steep Slope Soils

Symbol	Soil Type	Characteristics	Slope
22E	Colton	loamy fine sand,	15-50%
60D	Tunbridge-Berkshire	stony fine sandy loam	15-25%
61C	Tunbridge-Lyman	rock outcrop	8-15%
61D	Tunbridge-Lyman	rock outcrop	15-25%
72D	Berkshire	fine sandy loam	15-25%
73D	Berkshire	stony fine sandy loam	15-25%
76D	Marlow	fine sandy loam	15-25%
77D	Marlow	stony fine sandy loam	15-25%
77E	Marlow	stony fine sandy loam	25-50%
143D	Monadnock	stony fine sandy loam	15-25%
161E	Lyman-Tunbridge	rock outcrop	25-50%
365E	Berkshire & Monadnock	very stony fine sandy loam	25-50%
399	Rock outcrop	rock outcrop	8-50%
526E	Caesar	loamy sand	15-50%

These soils are found on the sides of hills, along ridges and as rocky outcrops void of soils. Ranging in slope from 8% to 50%, these soils are classified as having low and/or very low development potential because of steep slope, exposed or shallow bedrock and the lack of adequate corrective measures capable of increasing the development potential of such sites.
